Kunzea toelkenii

COMMON NAME Bay of Plenty kānuka

SYNONYMS None - first described in 2014

FAMILY Myrtaceae

AUTHORITY Kunzea toelkenii de Lange

FLORA CATEGORY Vascular – Native

ENDEMIC TAXON Yes

ENDEMIC GENUS No

ENDEMIC FAMILY No

STRUCTURAL CLASS Trees & Shrubs - Dicotyledons

CHROMOSOME NUMBER 2n - 22

CURRENT CONSERVATION STATUS 2017 | Threatened – Nationally Critical | Qualifiers: DP, RR

PREVIOUS CONSERVATION STATUS 2013 | Threatened – Nationally Vulnerable

BRIEF DESCRIPTION

Shrubs of small trees of active sand country; bearing numerous trunks, these much-twisted; base of trunks often suckering, suckering growth trailing. Branches often pendulous, very leafy, bearing clusters of small white flowers. Branchlet hairs in mixtures on long appressed and short erect. Leaves $2.6-8.5 \times 0.6-2.5$ mm. Flowers borne in 'corymbiform' clusters, white with a red centre—late season flowers often male. Fruit a small dry capsule $2.1-3.0 \times 2.5-3.7$ mm.

DISTRIBUTION

Endemic. New Zealand: North Island (Bay of Plenty near Thornton and on islands of the Ohiwa Harbour, formerly from Papamoa to Thornton and Ohiwa Harbour).

HABITAT Active sand dunes.

Fruit. Whakatane (from a specimen collected by Jacqui Bond). Photographer: Jeremy R. Rolfe, Date taken: 22/01/2018, Licence: CC BY.

DETAILED DESCRIPTION

Shrubs up to 4 × 6 m; 'juveniles' usually prostrate and trailing up to 4 m diameter, often flowering, eventually developing several, central, ascending branches; 'adults' forming widely spreading (up to 2 m diam.), flat-topped shrubs, with pendulous branches and branchlets; trunk bases usually bearing epicormic, prostrate growth spreading up to 4 m diam. Trunk 1–10, ascending to suberect, highly contorted, twisted, bent, and spiralled, 0.10–0.40 m d.b.h.; mostly arising from the top of a broad rootstock. Bark coriaceous, grey or grey-brown, ± elongate, cracking into highly irregular pieces with rather sinuous margins; detaching inwards. Branches numerous, widely spreading, ± serpentine, flexuose, pendulous and interwoven; branchlets numerous, slender, pendulous, leafy; those of epicormic growth, straight, prostrate or pendulous if arising from basal half of trunk,; indumentum copious; hairs of two types: long, appressed, flexuose to 0.26 mm long, and smaller divergent hairs, with curled and spiralled apices 0.04–0.18 mm. Leaves with lamina 2.6–8.5 × 0.6–2.5 mm, dark glossy green or bright-green, obovate, clavate, to broadly oblanceolate; apex sharply acute to apiculate, base attenuate; glabrous; lamina margin finely to densely sericeous, hairs weakly flexuose, to 0.5 mm long, aligned in 1–2 uninterrupted rows meeting just short of leaf apiculus. Inflorescence 1–10-flowered corymbiform botryum up to 40 mm long; inflorescences at the ultimate branchlet terminus uncommon (except in trailing epicormic growth), these elongated (up to 80 mm long) bearing well developed terminal vegetative growth, often with the uppermost flowers male. Pherophylis deciduous, initially foliose, soon squamiform, 0.4–1.6 mm long, foliose pherophylls green to bronze-green, shortly lanceolate to obovate, squamiform pherophylls amber-brown to brown, narrowly deltoid to ovate. Pedicels 1.6-3.8 mm long copiously invested with short, divergent to subantrorse, silky hairs. Flower buds bluntly clavate to obconic, rarely pyriform, apex flat prior to bud burst with calyx valves not meeting. Flowers 3.6–9.0 mm diam., often functionally male toward end of flowering season. Hypanthium $1.7-3.2 \times 2.8-4.3$ mm, green, dark green or red-green; obconic to funneliform, bearing five persistent calyx lobes; surface smooth, finely and rather densely puberulent; hairs silky. **Calyx lobes** 5, upright, 0.8–1.2 × 0.7–1.2 mm, persistent, ovate, broadly ovate to ovate-deltoid, glabrous except for ciliate margins. Receptacle pink at anthesis, darkening dark magenta or maroon-black at fertilisation. Petals 5-6, 1.5-2.8 × 1.5-2.6 mm, white, orbicular to very broadly ovate, apex obtuse to rotund, margins ± entire, oil glands colourless. Stamens 20–50 in 1–3 weakly defined whorls, filaments white. Anthers dorsifixed, 0.06–0.09 × 0.05–0.08 mm, testicular-oval to testicular-ellipsoid, latrorse. Pollen white. Anther connective gland prominent, pale lemon to pink when fresh, drying yellow to pale orange, spheroidal, finely papillate. Ovary absent in males flowers, 3-5 locular, each with 12-24 ovules in two rows on each placental lobe. Style absent in male flowers, 1.0–1.8 mm long, white; stigma capitate, scarcely wider than style, flat, greenish-white, cream or pale pink, surface papillate. Fruits 2.1–3.0 × 2.5–3.7 mm, light brown to grey, obconic, broadly obconic, to cupular. Seeds 0.50–1.02 × 0.52–0.68 mm, oblong, oblong-obovate, testa semi-glossy, amber, orange-brown to brown, surface coarsely reticulate.

MANAAKI WHENUA ONLINE INTERACTIVE KEY Key to the Myrtaceae of New Zealand

SIMILAR TAXA

Kunzea toelkenii is recognised by its uniquely suberect, sprawling growth habit, typically extensive suckering, by its mixed branchlet hairs, tendency to produce late season functionally male flowers, and also by its restriction to active sand dunes. Further differences are given by de Lange (2014).

FLOWERING September–November

FLOWER COLOURS White

FRUITING October–September

PROPAGATION TECHNIQUE

Easily grown from fresh seed. Can also be grown—with difficulty—from semi-hardwood and hardwood cuttings. Like all New Zealand *Kunzea*, this species prefers an open site, in full sun, planted in well drained soil.

THREATS

As *Kunzea* aff. *ericoides* (a) (AK 255350; Thornton) *Kunzea toelkenii* was listed by the New Zealand Threatened Vascular Plant Panel (de Lange et al. 2013b) as 'Threatened – Nationally Vulnerable', qualified 'Range Restricted (RR)'. For a detailed assessment of this listing see de Lange (2014). When myrtle rust (*Austropuccinia psidii*) was detected in New Zealand (May 2017) the conservation status was upgraded as a precautionary measure to 'Threatened – Nationally Critical' because, on best advice, it was believed that no indigenous Myrtaceae had resistance to the myrtle rust disease (de Lange et al. 2018). Currently there have been no reports of infected wild trees of *Kunzea* but inoculation trials of the New Zealand species has demonstrated they are susceptible, and further that over time, infected specimens will die. Only time will tell if wild populations of *Kunzea* will be threatened by this rust fungus.

Myrtle rust (*Austropuccinia psidii*) is an invasive fungus that threatens native myrtle species. Learn more <u>myrtlerust.org.nz</u>.

ETYMOLOGY

kunzea: Named after Gustav Kunze (4 October 1793, Leipzig -30 April 1851), 19th century German botanist from Leipzig who was a German professor of zoology, an entomologist with an interest mainly in ferns and orchids **toelkenii**: The epithet 'toelkenii' honors Australian botanist Hellmut R. Toelken (1939–) whose preliminary investigation of the Kunzea ericoides complex established that the species was a New Zealand endemic and worthy of further taxonomic segregation.

NOTES

de Lange (2014) attributed the discovery of *Kunzea toelkenii* incorrectly—the species was first recognised as potentially distinct by Beadel (1985, 1987).
